SQL Cheat Sheet: Accessing Databases using Python

QLite

	Suche								
Topic	Syntax	Description	Example						
connect()		Create a new database and open a database connection to allow spited to work with it. Call spited connect()—to create a connection to the database INSTRUCTOR.db in the current working directory, implicitly creating It if it does not exist.	1 import solites 2 con = sqlite1.convect('INSTRUCTOR.db')						
cursor()	con.cursor()	To execute SQL statements and fetch results from SQL quaries, use a database cursor. Call concursor() to create the Cursor.	1 cursor_obj * con.cursor()						
execute()		The cescuts imethod in Python's SOLIte library allows to perform SOL commands, including retrieving data from a table using a query like "Select" from table, name." When you execute this command, the result is obtained as a collection of table data stored in an object, typically in the form of a list of lists.	1 cursor_obj.execute('''insert into INSTRUCTOR values (1, 'Rav', 'Abuja', 'TORONTO', 'CA')''') 2						
fetchall()	cursor_obj.fetchall()	The <u>fetchall()</u> method in Python retrieves all the rows from the result set of a query and presents them as a list of tuples.	1 statement = ''SELECT * FROM INSTRUCTOR''' 2 cursor_obj.seccute(statement) 3 output_all = cursor_obj.fetchall() 4 for row_all in output_all: 5 print(row_all) = @						
felchmany()		The fetchway() method retrieves the subsequent group of rows from the result set of a query rather than just a single row. To fetch a few rows from the table, use fetchmany(numberofrows) and mention how many rows you want to fetch.	1 statement = '''SELECT ' FROM INSTRUCTON''' 2 curson_obl_secente(statement) 3 output_many = curson_obl_fetchmany(2) 4 for rea_many in output_many: 5 print(row_many) @						
read_sql_query()	read_sql_query()	read_sel_query() is a function provided by the Pandas library in Python, and it is not specific to MySQL, it is a generic function used for executing SQL queries on various database systems, including MySQL, and retrieving the results as a Pandas DataPrane.	1 df * pd.read_sql_query('select * from instructor;', comn)						
shape		It provides a tuple indicating the shape of a DataFrame or Series, represented as (number of rows, number of columns).	1 df.:hape						
close()		conclose() is a method used to close the connection to a MySQL database. When called, it terminates the connection, releasing any associated resources and ensuring the connection is no longer active. This is important for managing database connections efficiently and preventing resource leaks in your MySQL database interactions.	1 con.close()						
CREATE TABLE		The CRATE TABLE statement is used to define and create a new table within a database. It specifies the table's name, the structure of its columns (including data types and constraints), and any additional properties such as indexes. This statement essentially sets up the blueprint for organizing and storing data in a structured format within the database.	1 CREATE TABLE INTERNATIONAL_STUDENT_TEST_SCORES (de> 2 country VMCMAR(99), de> 3 first_name VMCMAR(99), de> 4 last_name VARCMAR(99), de> 5 test_score_INT 6);						
barplot()	seaborn.barplot(se"s-axis_vzzriable", y="y-axis_vzzriable", data-data)	subsens barplot() is a function in the Seaborn Python data visualization torsey used to create a bar plot, also known as a bar chart. It is particularly used to display the relationship between a categorical variable and a numeric variable by showing the avertige value for each category.	1 Import seaborn 2 seaborn.barplot(x="Test_Score",y="frequency", data=dataframe)						
read_csw()	<pre>df = pd.read_csv('file_path.csv')</pre>	read_csv() is a function in Python's Pandas Ibrary used for reading data from a Comma-Separated Values (CSV) tile and loading it into a Pandas DataFrame. It's a common method for working with tabular data stored is CSV format	1 import pandas 2 df = pandas.read_cov('https://data.cityofthicago.org/resource/jcxq-k0xf.cov')						
to_sql()	df.to_sql('table_name', indexofalse)	df. to solf) is a method in Pandas, a Python data manipulation library used to write the contents of a DataFrame to a SOL database. It allows to take data from a DataFrame and store it structurally within a SOL database table.	1 import pandas 2 df = pandas.read_csv('https://data.cityofchicago.org/resource/jcxq-k9xf.csv') 3 df.to_sql('chicago_socioeconomic_data'', com, if_exists='replace', index=False,method='multi') @						
read_sql()		read_53() is a function provided by the Pandas library in Python for executing SOL quaries and retrieving the results into a DataFrame from an SOL database. It's a convenient way to integrate SOL database interactions into your data analysis workflows.	1 selectQuery = "select * from INSTRUCTOR" 2 df = pandas.read_sql(selectQuery, com)

Db2							
Topic	Syntax	Description	Example				
connect()	com = lbm_d0.connect('DATAMASE-dbname; HOST-bostname; PORT-port;UID-username;	Ibm_Onconnect() Is a Python function provided by the ibm_Ob library, which is used for establishing a connection to an IBM DibC of IBM DibC Vibrathouse database. It's commonly used in applications that need to interact with IBM DibC databases from Python.	1 inport Ibm_db 2 com = Ibm_db.commet('CATAMASE-mydb; 3 inST-example.com;VGHT-30000;UD:myuser; 4 VAD-mypassord;', '', '') (@)				
server_info()			1 server = 1bm_db.server_info(com) 2 print ("DBMS_UNE: ", server_DBMS_UNE) 3 print ("DBMS_UNE: ", server_DBMS_UNE) 4 print ("DBMS_UNE: ", server_DBMS_UNE) @				
close()	_con.close()	con_clase() is a method used to close the connection to a disc database. When called, it terminates the connection, releasing any associated resources and ensuring the connection is no longer active. This is important for managing database connections efficiently and preventing resource leaks in your dis2 database interactions.	1 con.close()				
exec_immédiate()	sql_statement = "SQL statement goes here" stst = 1bm_dh.exec_immediate(conn, sql_statement)	ibe_db.exec_tasediste() is a Python function provided by the lbm_db library, which is used to execute an SOL statement immediately without the need to prepare or bind it. It's commonly used for executing SOL statements that don't require injud parameters or don't need to be prepared in advance.	8 Lets first drop the table INSTRACTOR in case it exists from a previous attempt. 2
