Cheat Sheet: Python Data Structures Part-2

Dictionaries

2023-10-11 14:37:21 Wes				
Package/Method	Description	Code Example		
Creating a Dictionary	A dictionary is a bullit-in data type that represents a collection of key-value pairs. Dictionaries are enclosed in curly braces 1	Example: 1 dict_name = () Screates an empty dictionary 2 person = ("name": "John", "age": 34, "City": "New York") @		
Accessing Values	You can access the values in a dictorary using their corresponding to the corresponding to th	Symbox		
Add or modify	truents a new key-value pair into the dictionary. If the key already exists, the value will be updated; otherwise, a new entry is created.	Symbox 1 dict_name[key] = value ② Example: 1 person["Country"] = "USA" e A new entry will be created. 2 person["City"] = "Chicago" # Update the existing value for the same ③		
del	Removes the specified key-value pair from the dictionary, Raises a Regirror if the key does not exist.	Syntax: 1 del dict_name[key] ② Example: 1 del person["Country"] ②		
update()	The wedste() method merges the provided dictionary into the existing dictionary, adding or updating key-value pairs.	Symbax		
clear()	The County method empties the dictionary, removing all key-value pairs within it. After this operation, the dictionary is still accessible and can be used further.	Symbax 1 dict_name.clear() © Doumple: 1 grades.clear() ©		
key existence	You can check for the existence of a key in a dictionary using the keyword	Dampic 1 if "name" in person: 2 print("have exists in the dictionary.") @		
сору()	Creates a shallow copy of the dictionary. The new dictionary contains the same key-value pairs as the original, but they remain distinct objects in memory.	Symbox 1 new_dict = dict_name.copy() @ Example: 1 new_person = person.copy() 2 new_person = dict(person) # another way to create # copy of dictions @		
keys()	Retrieves all keys from the dictionary and converts them into a list. Useful for iterating or processing keys using list methods.	Symtax		
values()	Extracts all values from the dictionary and converts them into a list. This list can be used for further processing or analysis.	Symbax		
items()	Retrieves all key-value pairs as tuples and converts them into a list of tuples. Each tuple consists of a key and its corresponding value.	Symbox		

Sets

Package/Method	Description		Code Example		
add()	Elements can be added to a set using the "add()" method. Duplicates are automatically removed, as sets only store unique values.	Syntax 1 Examp	set_name.add(element)	අ	
		1	fruits.add("mango")	æ	
		Syntax 1	set_name.clear()	ළු	
clear()	The 'Clear()' method removes all elements from the set, resulting in an empty set. It updates the set in-place.	Examp	ie:		
		1	fruits.clear()	අා	
		Syntax 1	new_set = set_name.copy()	æ	
copy()	The "copy()" method creates a shallow copy of the set. Any modifications to the copy won't affect the original set.	Example:			
			new_fruits = fruits.copy()	æ	
		Examp	le:		
Defining Sets	A set is an unordered collection of unique elements. Sets are enclosed in curly braces (j). They are useful for storing distinct values and performing set operations.		<pre>empty_set = set() #Creating an Empty Set fruits = {"apple", "banana", "orange"}</pre>		
		Syntax			
			set_name.discard(element)	æ	
discard()	Use the 'discardi)' method to remove a specific element from the set. Ignores if the element is not found.	Example:			
			fruits.discard("apple")	æ	
		Syntax			
			is_subset = set1.issubset(set2)	¢	

issubset()	The 'issubset()' method checks if the current set is a subset of another set. It returns True if all elements of the current set are present in the other set, otherwise False.	Example:
issuuseij		1 is_subset = fruits.issubset(colors)
issuperset()	The "issupersetl)" method chacks if the current set is a superset of another set. It returns True if all elements of the other set are present in the current set, otherwise False.	Syntax: is_superset = set1 issuperset(set2) Example: 1 is_superset = colors.issuperset(fruits)
рор()	The 'popt)' method removes and returns an arbitrary element from the set. It raises a 'KeyError' if the set is empty. Use this method to remove elements when the order doesn't matter.	Symax
remove()	Use the 'remove()' method to remove a specific element from the set. Raises a 'KeyErro' if the element is not found.	Syntax
Set Operations	Perform various operations on sets: 'union', 'intersection', 'difference', 'symmetric difference'.	Syntax 1 union_set = set1.union(set2) 2 intersection_set = set1.intersection(set2) 3 difference_set = set1.difference(set2) 4 sym_diff_set = set1.symetric_difference(set2) 1 combined = fruits.union(colors) 2 common fruits.intersection(colors) 3 unique_to_fruits = fruits.difference(colors) 4 sym_diff = fruits.symmetric_difference(colors)
update()	The 'update()' method adds elements from another fertable into the set. It maintains the uniqueness of elements.	Syriax 1 set_name.update(iterable) Q
